# Outline

- 1. Introduction
- 2. Key Elements
- 3. Space-Time-State Network Flow Models
- 4. Decomposition: Dantzig-Wolfe decomposition
- 5. Decomposition: Column-pool based approximation
- 6. Discussion and Preliminary Experiments
- 7. Summary

How to optimize demand, supply and infrastructure?

#### **Vehicle Routing Problem:**

#### Input:

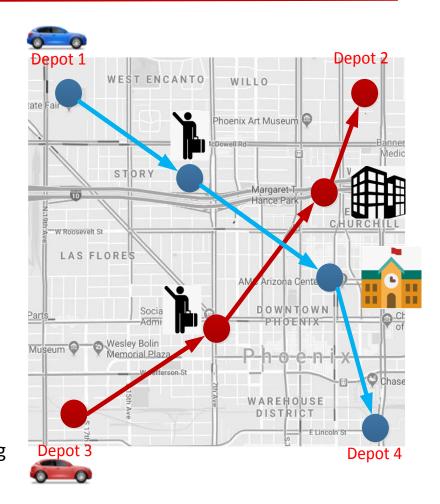

- **Network**: Virtual point-to-point network
- Passenger trip request: has specific pick-up and drop-off location with time windows
- ☐ Vehicle carrying capacity: considered

#### Goal:

■ System Optimal

#### Output:

- ☐ Vehicle-to-passenger assignment: will be found
- ☐ Variable: discrete vehicle routing and scheduling

### **Traffic Assignment Problem:**

#### Input:

- ☐ **Network**: Physical traffic network
- ☐ Road capacity: capture road congestions
- ☐ Origin and Destination: vehicle has the same origin

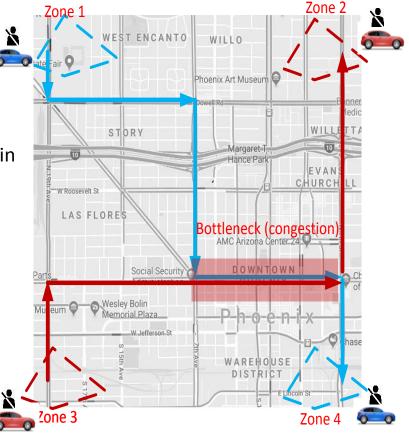

and destination with the assigned passengers

#### Goal:

☐ System Optimal or User Equilibrium

#### Output:

continuous vehicle flow on links/paths

#### Uncertain elements from the current to the future

#### **Travel Demand**

- Trip request: origin and destination with self-owned vehicles or submit pickup and drop-off locations with time windows for mobility providers
- Trip privacy: alone or rideshare
- Trip mode: single mode or multiple modes

#### **Vehicle Supply**

- Driving mode: selfdriving or humandriven
- Routing behavior: selfish or coordinated
- Ownership: household or mobility providers

#### Infrastructure

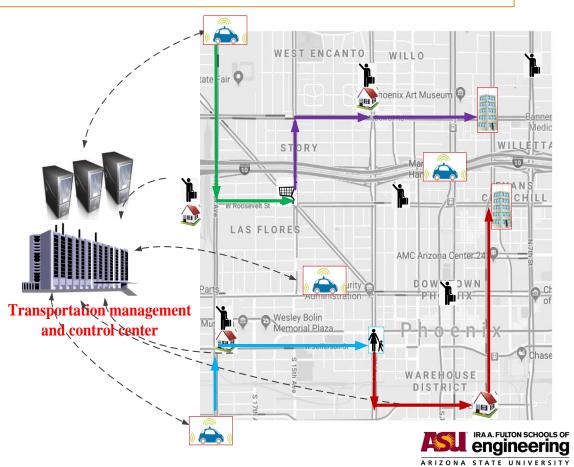

- Link/Lane capacity
   change
- Sensor and communication (V2V, V2I)
- Smart Transportation network (road, parking, depots, bus line, rail transit line, etc.)

Special scenario: integration of travel demand, vehicle supply and infrastructure capacity

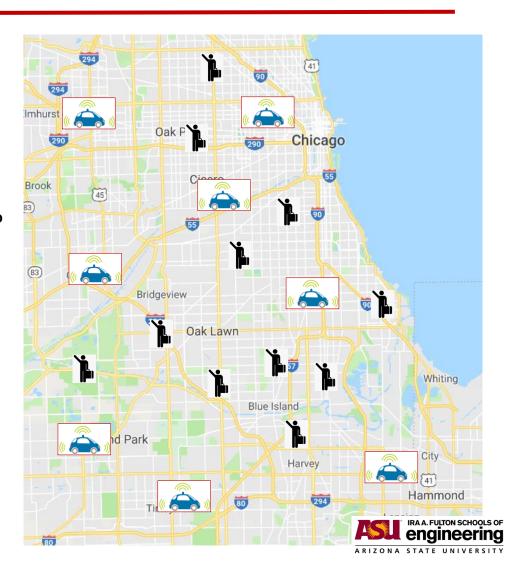

### **Keywords:**

- □ Physical traffic network to consider traffic congestion
- ☐ Trip requests with Pickup and delivery with time windows
- Autonomous vehicles with carrying capacity for ride sharing
- □ Central control (System optimal)

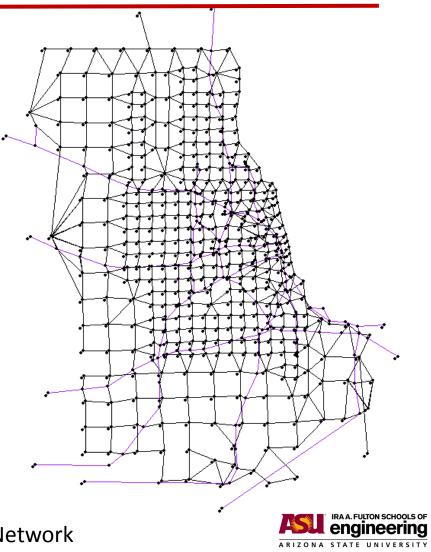

### **Key questions:**

- How many autonomous vehicles do we need?
- How many passengers can we serve?
- How to capture the new traffic congestion?
- What is the best vehicle routing and vehicle-to-passenger assignment solution?

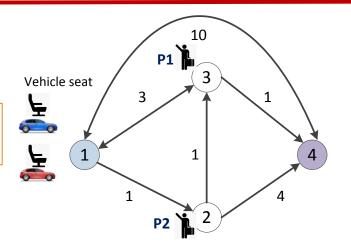

# of nodes	1320	
# of links	5431	
optimization time horizon (min)	60	
arc capacity each min (vehicle)	35	
# of passenger groups with same OD and departure time	2226	
Total trip requests	4452	
# of vehicle depots	243	

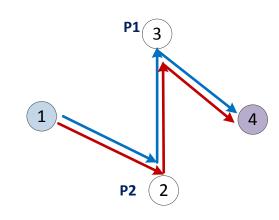

Chicago Sketch Network

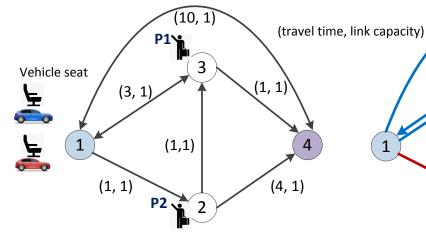

# **Link Capacity**

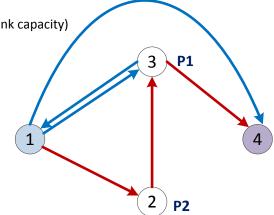

Without link capacity: Total cost is 6

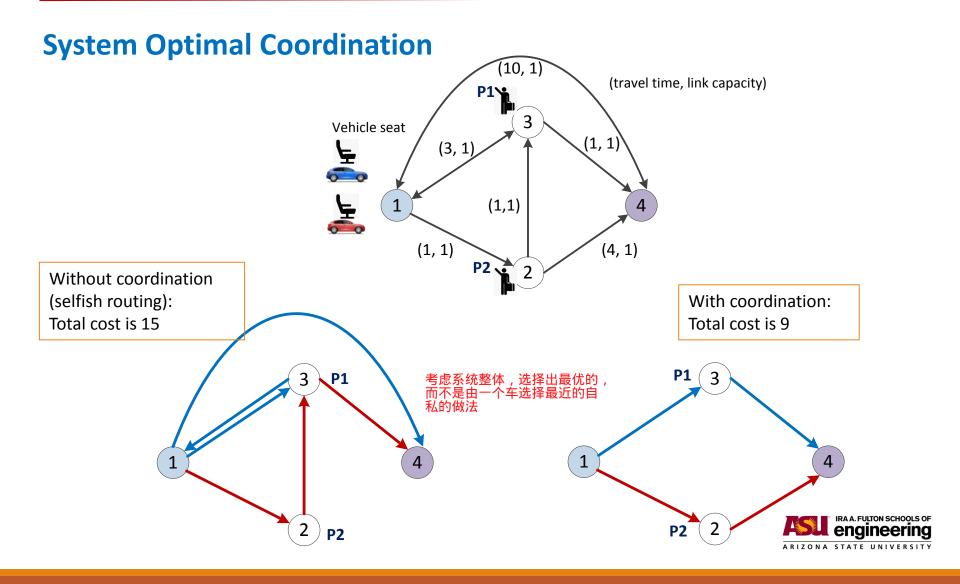

With link capacity: Total cost is 15

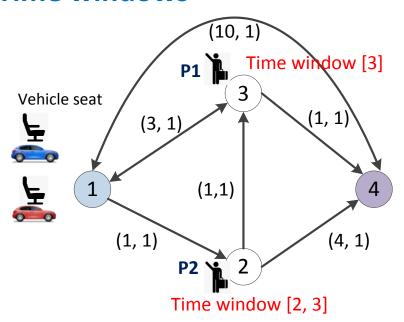

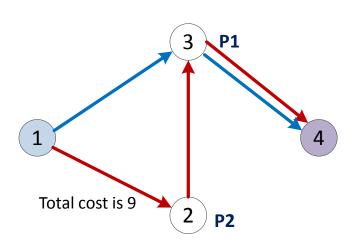

#### **Time windows**

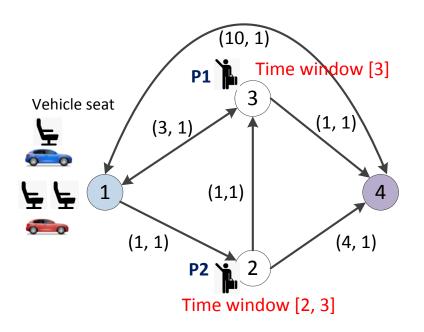

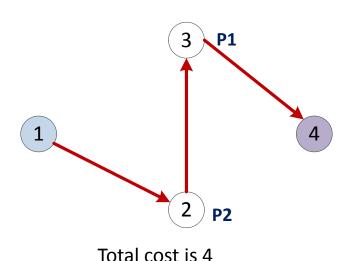

- ☐ The red vehicle can wait until time 3 to pick up passenger 2, so the blue vehicle can pick up passenger 1 at exact time 3.
  - 成本最小
- The optimal result doesn't only optimize the vehicle routing, but also the departure time of picked up passengers.

时间窗内

### Ridesharing (vehicle carrying capacity)

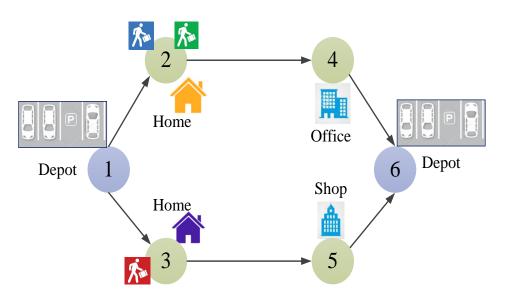

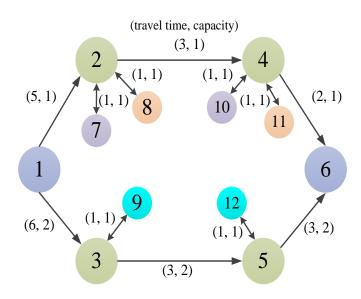

- ☐ When the red vehicle's carrying capacity is increased to 2, the total cost is reduced to 4 from 9;
- ☐ Only the red vehicle is required to serve the trip requests.

#### Passenger trip requests: pickup and drop-off locations and time windows

(a) Physical transportation network with vehicles and trip requests

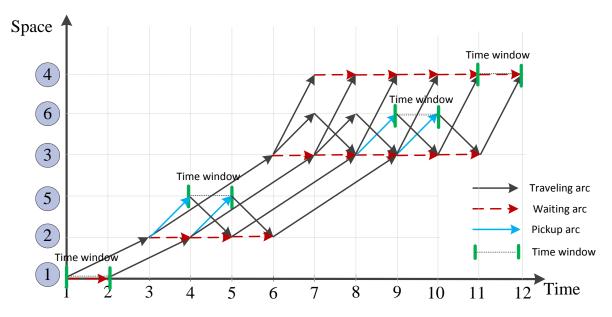

(b) Modified transportation network with virtual pickup and delivery nodes and links

Add virtual pick-up and drop-off nodes and links for each passenger

由实际路网---构造的虚拟路网,增加虚拟接取送达点和接取送达弧

Time-extended Space-time network construction for physical path  $1 \rightarrow 2 \rightarrow 4 \rightarrow 6$ 

Arc (i,j,t,s) with capacity
Vertex (i,t), (j,s)

Passenger pickup time windows and locations are embedded in this network

等待弧只存在于实际路网点?

Space-time network

### **Vehicle Carrying States for passenger pickup and drop-off:**

which passengers are being carried by this vehicle:

#### To record the passenger service status:

0: the passenger is not served;

1: under served (picked up but not delivered);

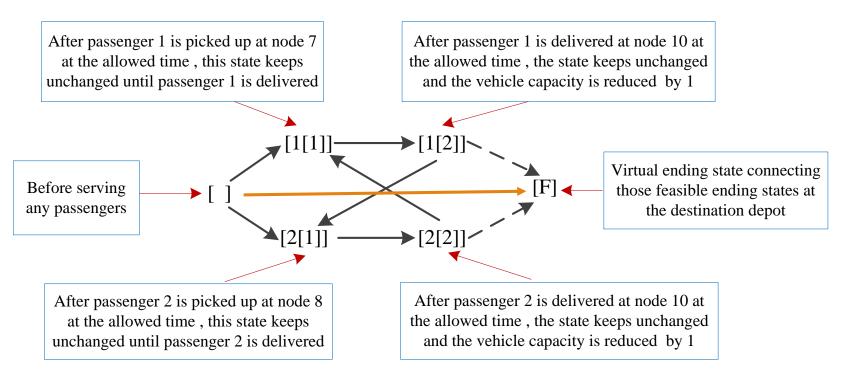

2: finished (delivered)

**Example:** In the case: if vehicle capacity is 1 and 2 passengers trip requests,

All possible states: [], [1[1]], [1[2]], [2[1]] or [2[2]]

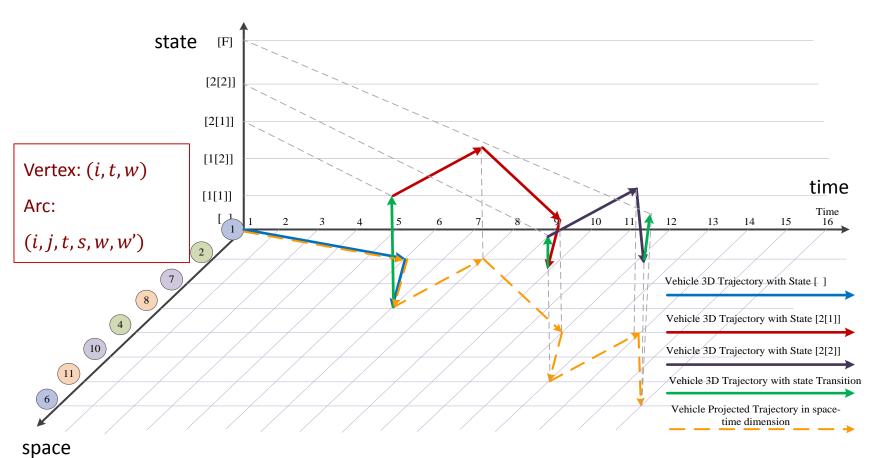

# Vehicle State Transition with specific pickup and drop-off locations within time windows

Vehicle carrying state transition graph

One possible vehicle trajectory in a space-time-state network

#### **Arc-based agent-based formulation:**

Objective function:

$$Min Z = \sum_{a} \sum_{(i,j,t,s,w,w')} (c^{a}_{i,j,t,s,w,w'} \times x^{a}_{i,j,t,s,w,w'})$$
 (1)

Subject to,

(i) Vehicle supply: Arc-based flow balance constraint for each vehicle

$$\sum_{i,t,w:(i,j,t,s,w,w')} x_{i,j,t,s,w,w'}^{a} - \sum_{i,t,w:(j,i,s,t,w',w)} x_{j,i,s,t,w',w}^{a} = \begin{cases} -1 & j = O(a), s = DT(a), w = [0,0,...,0] \\ 1 & j = D(a), s = T, w = [0,0,...,0] \\ 0 & otherwise \end{cases}, \forall a \quad (2)$$

(ii) **Travel demand**: Passenger p's pick-up request constraint

$$\sum_{a} \sum_{i,t,s:(i,j,t,s,w,w') \in A(p)} x_{i,j,t,s,w,w'}^{a} = 1, \forall p$$
(3)

(iii) Infrastructure supply: Tight road capacity constraint (endogenous congestion)

$$\sum_{a} \sum_{w} x_{i,j,t,s,w,w'}^{a} \le cap_{i,j,t,s}, \forall (i,j,t,s)$$

$$\tag{4}$$

(iv) Binary definitional constraint

$$x_{i,j,t,s,w,w'}^{a} \in \{0,1\} \tag{5}$$

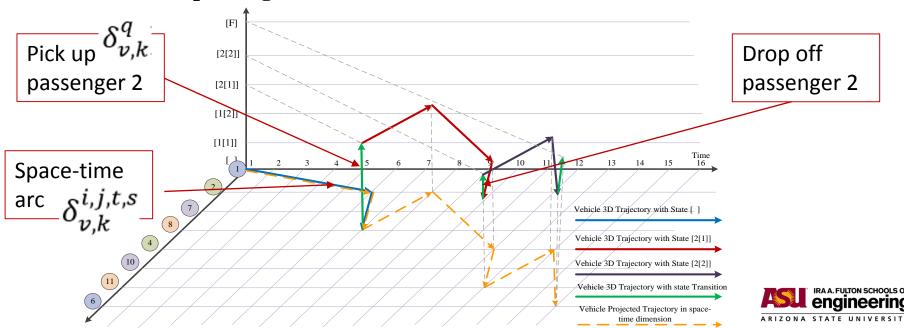

**Remark**: state definition *w* differs for passenger pickup only and passenger pickup and drop-off

#### Path-based flow-based formulation:

#### **Assumptions:**

- (1) **Vehicles** and **Passengers** can be grouped by its origin, destination and required service time period
- (2) All possible paths of vehicle groups can be enumerated in advance.
- (3) The **space-time-state** path of each vehicle group has the **mapping** information about **vehicle-to-passenger** and **vehicle-to-arc** relation.

#### **Path-based flow-based formulation:**

$$\min \sum_{(v,k)} (c_v^k \times y_v^k) \tag{6}$$

Subject to

(i) **Vehicle supply:** Path-based vehicle group flow balance constraint:

$$\sum_{k} y_{\nu}^{k} = d(\nu), \forall \nu \tag{7}$$

(ii) **Travel demand**: Pickup requests on passenger group q:

$$\sum_{(v,k)} (y_v^k \times \delta_{v,k}^q) = g(q), \forall q$$
 (8)

(iii) Infrastructure supply: Road capacity constraints (endogenous congestion):

$$\sum_{(v,k)} (y_v^k \times \delta_{v,k}^{i,j,t,s}) \le cap_{i,j,t,s}, \forall (i,j,t,s)$$

$$\tag{9}$$

(iv) Positive continuous variable:

$$y_{\nu}^{k} \ge 0 \tag{10}$$

### Simplified format of our models

#### 1. Primal problem

$$\min cx$$

$$Ax = b$$

$$Bx \le d$$

Flow-balance constraint

Coupling constraint (trip request, link capacity)

Restricted / master problem

#### 2. Lagrangian Relaxation

$$\min cx + \mu(d - Bx)$$

$$Ax = b$$

#### 3. Cutting plan method

$$max_{\mu} \min_{x} [cx + \mu(d - Bx)]$$
$$Ax = b$$

#### 4. Column generation/DW

$$\min c(\sum_{i} \lambda_{i} \times x_{i})$$

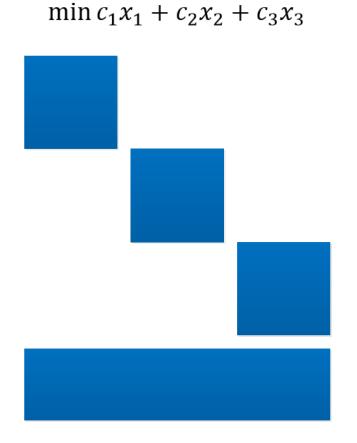

$$B \sum_{i} \lambda_{i} \times x_{i} \le d$$

$$\sum_{i} \lambda_{i} = 1$$

$$\lambda_{i} \ge 0$$

$$\min cx - \mu Bx - \pi$$
$$Ax = b$$

Subproblems

#### Objective function

$$a_1x_1=b_1$$

$$a_2x_2=b_2$$

Flow-balance constraint for each vehicle

$$a_3x_3=b_3$$

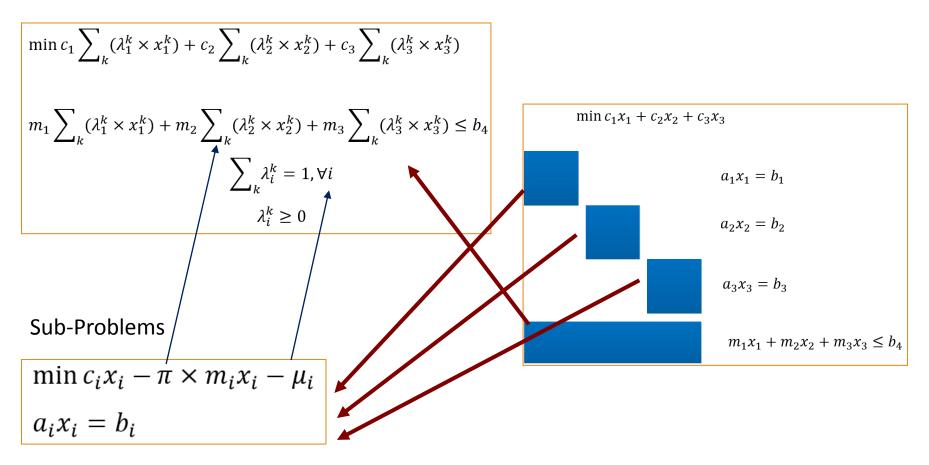

$$a_4 x_1 + a_5 x_2 + a_6 x_6 \le b_4$$

### Coupling constraints

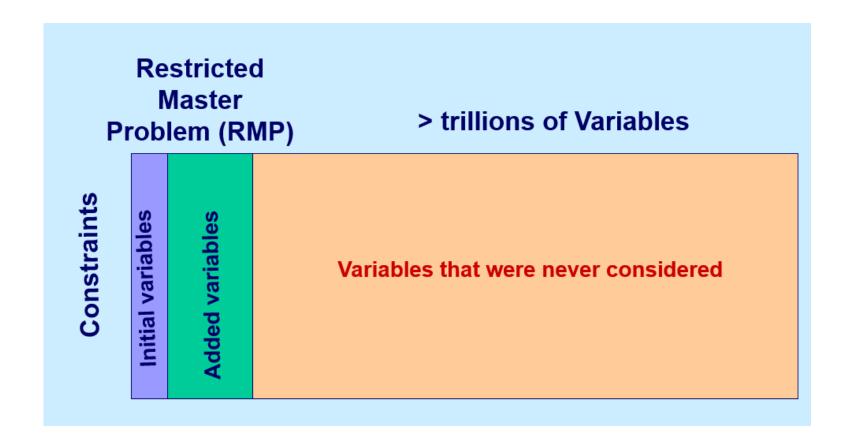

(passenger pickup, road capacity)

#### **Restricted Master Problem**

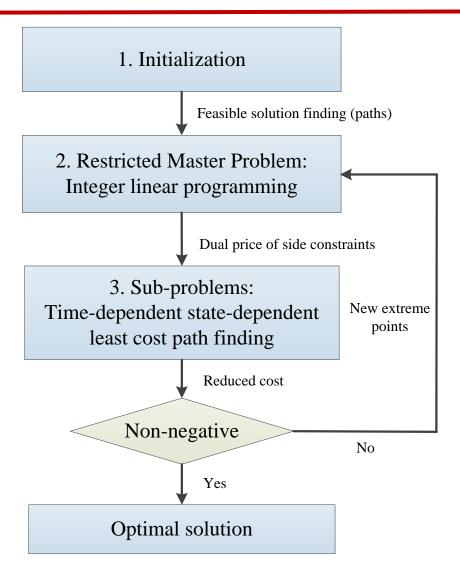

https://ocw.mit.edu/courses/sloan-school-of-management/15-082j-network-optimization-fall-2010/lecture-notes/

#### **Restricted master problem**

Objective function

$$Min \sum_{v} \sum_{k} (c_{a,o,d}^{k} \times \lambda_{a,o,d}^{k})$$

Passenger pickup constraint

$$\sum_{v} \sum_{k} (\lambda_{a,o,d}^{k} \times \delta_{k,p}^{a,o,d}) = 1, \forall p$$

Space-time arc capacity constraint

$$\sum_{a,o,d} \sum_{k} (\lambda_{a,o,d}^{k} \times \beta_{a,o,d,(i,j,t,s)}^{k}) \leq cap_{i,j,t,s}, \ \forall (i,j,t,s)$$

Path weight constraint

$$\sum_{k} \lambda_{k}^{a,o,d} = 1, \forall (a,o,d)$$

$$\lambda_{k}^{a,o,d} = \{0,1\}$$

#### Subproblems (TDSDSP)

The sub-problem for each vehicle *a*:

$$\min Z' = \sum_{(i,j,t,s,w,w')} (c^{a}_{i,j,t,s,w,w'} \times x^{a}_{i,j,t,s,w,w'}) - \sum_{p} \sum_{(i,j,t,s,w,w') \in A(p)} (\pi_{p} \times x^{a}_{i,j,t,s,w,w'}) - \sum_{(i,j,t,s)} (\mu_{i,j,t,s} \times \sum_{w} x^{a}_{i,j,t,s,w,w'}) + \omega_{a}$$

Flow balance constraint for each vehicle

$$\sum_{i,t,w:(i,j,t,s,w,w')} x_{i,j,t,s,w,w'}^{a} - \sum_{i,t,w:(j,i,s,t,w',w)} x_{j,t,s,t,w',w}^{a} = \begin{cases} -1 & j = O(a), s = DT(a), w = [0,0,\dots,0] \\ 1 & j = D(a), s = T, w = [0,0,\dots,0] \\ 0 & otherwise \end{cases}, \forall a$$

Dual price of of passenger pickup constraints

Dual price of congestion constraints

Dual price of path weight constraints

Each column is a path with information and connection of passenger trip requests,

[2[2]] [2[1]] [1[2]] [1[1]]

and vehicle passed space-time arcs

$$\min \sum_{(o,d,k)} (c_{o,d}^k \times y_{o,d}^k)$$

requests on passenger group 
$$q$$
:
$$\sum_{(o,d,k)} (y_{o,d}^k \times \delta_{o,d,k}^q) = g(q), \forall q$$

(2) Road capacity constraints:

$$\sum_{(o,d,k)} (y_{o,d}^k \times \delta_{o,d,k}^{i,j,t,s}) \leq cap_{i,j,t,s}, \forall (i,j,t,s)$$

(3) Positive continuous variable (path vehicle flow):

$$y_{o.d}^k \ge 0$$

Compared with arc-based formulation, column-based model greatly reduces the number of variables.

Vehiçle 3D Trajectory with State [2 Vehicle 3D Trajectory with State [2] Vehicle 3D Trajectory with state Transition

 $\delta^q_{v,k}$  Incidence matrix of column with passenger trip requests

Column\ trip requests	p1	p2	р3	р4

y2	0	1	0	1
у3	0	0	1	1

 $\delta^{i,j,t,s}_{v,k}$  Incidence matrix of column with arc

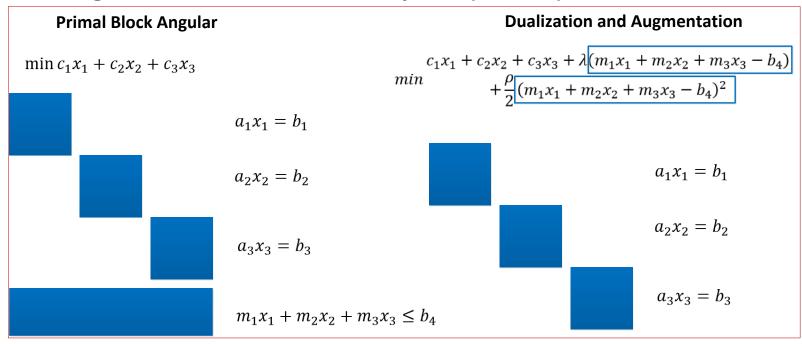

Column\space- time arc	arc 1(i,j,t,s)	arc 2(i,j,t,s)	arc 3(i,j,t,s)	arc 4(i,j,t,s)
y1	1	0	0	1
y2	0	1	1	0
у3	1	0	0	1

#### **Alternating Direction Method of Multipliers (ADMM)**

#### **Objective function:**

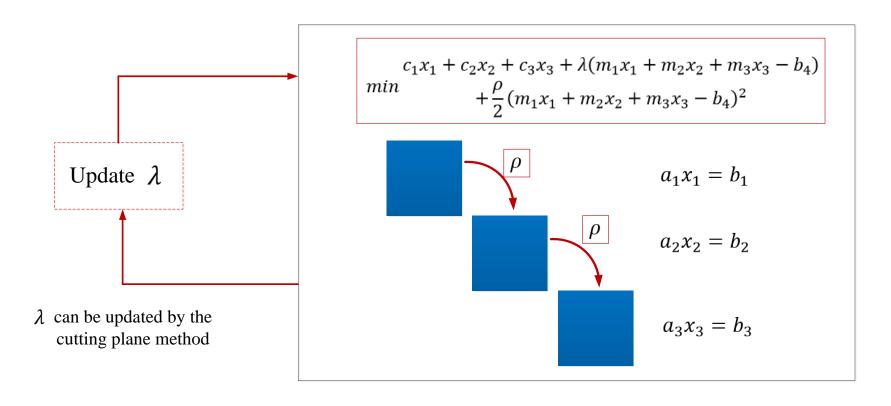

$$L(\mathbf{x},\lambda,\rho) = c_1x_1 + c_2x_2 + c_3x_3 + \lambda(m_1x_1 + m_2x_2 + m_3x_3 - b_4) + \frac{\rho}{2}(m_1x_1 + m_2x_2 + m_3x_3 - b_4)^2$$

**Solutions:** 
$$x_3^{n+1} = argminL(x_1^{n+1}, x_2^{n+1}, x_3, \lambda^n, \rho)$$

**Multiplier update:** 
$$\lambda^{n+1} = \lambda^n + \rho(m_1x_1^{n+1} + m_2x_2^{n+1} + m_3x_3^{n+1} - b_4)$$

#### Sequentially solving each subproblem

### **Arc-based Agent-based formulation**

#### Objective function:

$$\begin{split} & Min \ Z = L(\boldsymbol{x}^{a}, \boldsymbol{\pi}_{p}, \boldsymbol{\pi}_{(i,j,t,s)}) = \sum_{a} \sum_{(i,j,t,s,w,w')} \left( c_{i,j,t,s,w,w'} \times \boldsymbol{x}_{i,j,t,s,w,w'}^{a} \right) + \\ & \sum_{p} [\boldsymbol{\pi}_{p} \times (\sum_{a} \sum_{(i,j,t,s,w,w') \in A(p)} (\boldsymbol{x}_{i,j,t,s,w,w'}^{a} \times \boldsymbol{\delta}_{i,j,t,s}^{a}) - 1)] + \frac{\rho_{1}}{2} \sum_{p} \left[ \sum_{a} \sum_{(i,j,t,s,w,w') \in A(p)} (\boldsymbol{x}_{i,j,t,s,w,w'}^{a} \times \boldsymbol{\delta}_{i,j,t,s,w,w'}^{a}) + \sum_{(i,j,t,s)} [\boldsymbol{\pi}_{(i,j,t,s)} \times (\sum_{a} \sum_{w} \boldsymbol{x}_{i,j,t,s,w,w'}^{a} - cap_{i,j,t,s})] + \frac{\rho_{2}}{2} \sum_{(i,j,t,s)} \left[ \sum_{a} \sum_{w} \boldsymbol{x}_{i,j,t,s,w,w'}^{a} - cap_{i,j,t,s} \right]^{2} \end{split}$$

#### At each iteration:

- Solve each sub-problem sequentially for each vehicle
- Each sub-problem is a time-dependent state-dependent shortest path problem for each vehicle
- Update Lagrangian multipliers for passenger pickup constraints and arc capacity constraints

#### ADMM for agent-based model

#### // initialization

Set up initial values for all <u>Lagrangian multiplers</u> and penalty parameters

for n = 1 to  $n_{max}$  // total number of iterations

for a = 1 to  $a_{max}$  //total number of vehicles

Find the time-dependent state-dependent shortest path for vehicle a with the fixed solution of other vehicles Update the network-arc costs based on the new solution of vehicle a for vehicle a + 1

end // vehicle

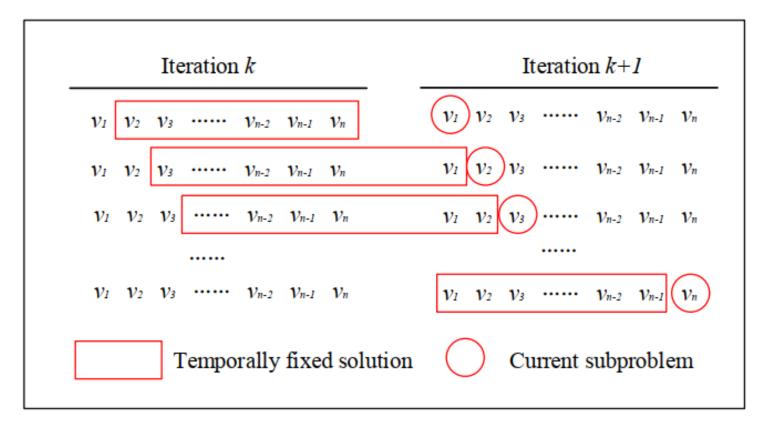

Update Lagrangian multipliers of passenger pickup constraints and arc capacity constraints end // iterations

At iteration n + 1 of ADMM:

$$\begin{split} x_a^{n+1} &= \arg\min \left\{ L(x_1^{n+1}, x_2^{n+1}, \dots, x_a, x_{a+1}^n, \dots, x_{a_{\max}}^n, \pmb{\pi}_p^n, \pmb{\pi}_{i,j,t,s}^n) \right\} \\ \pi_p^{n+1} &= \pi_p^n - \rho_1 [\sum_a \sum_{(i,j,t,s,w,w') \in A(p)} (x_{i,j,t,s,w,w'}^{a,n+1} \times \delta_{i,j,t,s}^a) - 1] \\ \pi_{i,j,t,s}^{n+1} &= \max \left\{ 0, \pi_{i,j,t,s}^n - \rho_2 [\sum_a \sum_w x_{i,j,t,s,w,w'}^{a,n+1} - cap_{i,j,t,s}] \right] \end{split}$$

#### At each iteration for each vehicle:

### Flow-based path-based ADMM:

### **Quadratic objective functions:**

$$\min \sum_{k} (c^k \times y^k) + \sum_{q} (\lambda_q \times \left[ \left( \sum_{k} (y^k \times \delta_q^k) - g(q) \right] \right) + \frac{\rho_1}{2} \sum_{q} \left( \left( \sum_{k} (y^k \times \delta_q^k) - g(q) \right)^2 + \sum_{i,j,t,s} (\mu_{i,j,t,s} \times \left[ \sum_{k} (y^k \times \delta_{i,j,t,s}^k) - cap_{i,j,t,s} \right] \right) + \frac{\rho_2}{2} \sum_{i,j,t,s} \left( \sum_{k} (y^k \times \delta_{i,j,t,s}^k) - cap_{i,j,t,s} \right)^2$$

Its Hessian Matrix can be derived as,

$$H = \begin{bmatrix} \sigma_{1} \sum_{p} \delta_{p}^{1} + \sigma_{2} \sum_{i,j,t,s} \delta_{i,j,t,s}^{1} & \sigma_{1} \sum_{p} \delta_{p}^{1} \delta_{p}^{2} + \sigma_{2} \sum_{i,j,t,s} \delta_{i,j,t,s}^{1} \delta_{i,j,t,s}^{2} & \dots & \sigma_{1} \sum_{p} \delta_{p}^{1} \delta_{p}^{k_{max}} + \sigma_{2} \sum_{i,j,t,s} \delta_{i,j,t,s}^{1} \delta_{i,j,t,s}^{k_{max}} \\ \sigma_{1} \sum_{p} \delta_{p}^{1} \delta_{p}^{p} + \sigma_{2} \sum_{i,j,t,s} \delta_{i,j,t,s}^{1} \delta_{i,j,t,s}^{2} & \sigma_{1} \sum_{p} \delta_{p}^{2} \delta_{p}^{k_{max}} + \sigma_{2} \sum_{i,j,t,s} \delta_{i,j,t,s}^{2} & \dots & \sigma_{1} \sum_{p} \delta_{p}^{2} \delta_{p}^{k_{max}} + \sigma_{2} \sum_{i,j,t,s} \delta_{i,j,t,s}^{k_{max}} \delta_{i,j,t,s}^{k_{max}} \\ \vdots & \vdots & \dots & \vdots \\ \sigma_{1} \sum_{p} \delta_{p}^{1} \delta_{p}^{k_{max}} + \sigma_{2} \sum_{i,j,t,s} \delta_{i,j,t,s}^{1} \delta_{i,j,t,s}^{k_{max}} & \sigma_{1} \sum_{p} \delta_{p}^{2} \delta_{p}^{k_{max}} + \sigma_{2} \sum_{i,j,t,s} \delta_{i,j,t,s}^{k_{max}} & \dots & \sigma_{1} \sum_{p} \delta_{p}^{k_{max}} + \sigma_{2} \sum_{i,j,t,s} \delta_{i,j,t,s}^{k_{max}} \end{bmatrix}$$

Since it is difficult to directly obtain its inverse matrix  $H^-$ , especially in large-scale networks, we apply ADMM to decompose the primal problem to sequentially solve the subproblem for each column.

### Flow-based path-based ADMM:

 $\square$  Solve each variable  $y_{o,d}^k$  sequentially by ADMM

$$y_k^{n+1} = \arg\min\{L(y_1^{n+1}, y_2^{n+1}, \dots, y_k, y_{k+1}^n, \dots, y_{k_{\max}}^n, \lambda_q^n, \mu_{i,j,t,s}^n)\}$$

At each iteration of ADMM, Lagrangian multipliers are updated as follows,

### Passenger group trip requests:

$$\lambda_q^{n+1} = \lambda_q^n + \rho_1(\left(\sum_k (y_k^n \times \delta_q^k) - g(q)\right))$$

### Arc capacity constraints:

$$\mu_{i,j,t,s}^{n+1} = \max\{0, \mu_{i,j,t,s}^n + \rho_2(\sum_k (y_k^n \times \delta_{i,j,t,s}^k) - cap_{i,j,t,s})\}$$

Projected Gradient Method (Rosen, 1960) to solve each subproblem

$$y_k^{n+1} = \arg\min\{L(y_1^{n+1}, y_2^{n+1}, \dots, y_k, y_{k+1}^n, \dots, y_{k_{\max}}^n, \lambda_q^n, \mu_{i,j,t,s}^n)\}$$

$$\begin{aligned} y_k^{n+1} &= \max \left\{ 0, y_k^n - \frac{1}{s} \times L(y_k^n)' \right\} \\ \text{Where } L(y_k^n)' &= c^k + \sum_q \lambda_q \times \delta_q^k + \rho_1 \left( \sum_q \delta_q^k \left( \left( \sum_k (y_k^n \times \delta_q^k) - g(q) \right) \right) + \sum_{i,j,t,s} \mu_{i,j,t,s} \times \delta_{i,j,t,s}^k \right. \\ &+ \rho_2 (\sum_{i,j,t,s} \delta_{i,j,t,s}^k (\sum_k (y_k^n \times \delta_{i,j,t,s}^k) - cap_{i,j,t,s})), \text{ and } s = \frac{\partial^2 L(x)}{\partial x^2} = \rho_1 \sum_q \delta_q^k + \rho_2 \sum_{i,j,t,s} \delta_{i,j,t,s}^k \end{aligned}$$

Projected Gradient Method has been used in solving the path-based nonlinear programming models in equilibrium traffic assignment (Larsson and Patriksson, 1992; Jayakrishnan et al, 1994; Florian et al., 2009), and it is more efficient, compared with arc-based nonlinear programming models, but needs more memory use.

Beam-search algorithm for finding the time-dependent state-dependent shortest paths:

```
//definition: vehicle: v, node: n, time: t, state: w, vehicle location-dependent time-dependent states:
     td\_state[v][n][t][w]
        for t = departure time to ending time T
           for n = 0 to total number of nodes N
3
              //beam-search: find the best k vehicle states with least travel costs from depot to current node and
4
                time
5
              state size = \min\{k, \text{ state size of vehicle } v \text{ at node } n \text{ and time } t\}
              for w = 0 to state size
6
                 Current node = n
                 for to node =1 to the outbound node size of current node
8
                     if (to node is passenger pickup or drop-off node)
9
                       Update the vehicle state td_state[v][n][t][w] with passenger pickup or drop-off,
                       current node, current time, travel cost from the depot to current node and time with benefits
10
                       of serving passengers, based on previous node n, previous time t and link travel time,
                       previous state w, and the whole state transition logic.
                     if (to node is physical network node)
11
                       Update the vehicle state td_state[v][n][t][w] with current node, current time and
12
                        current travel cost, and state w doesn't change.
13
                     if (to node is destination node of vehicle v)
                       Update the vehicle state td_state[v][n][t][w] and update the corresponding
                       Vector vehicle ending state [v], which will be used to find the least cost route for vehicle
14
                        v after all loops.
                  end // downstream node of one link
15
16
               end // states
17
            end // nodes
18
        end// times
```

### Discussion: path marginal cost calculation

### System-impact of adjusting one vehicle routing:

- System marginal vehicle travel cost
- System marginal passenger service benefit/cost

#### [Time window] [Time window]

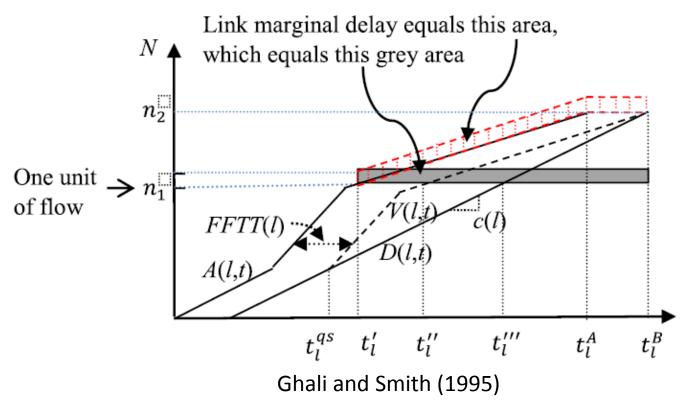

☐ Waiting time for individual: 4 min

### After adding one more person in the queue:

- □ Societal travel time: additional 4 min for each person behind:
  - +16 min, and the waiting time of added person is 4 min, so the system marginal waiting time is 20 min.
- Societal service benefit: some persons may not be served in their preferred time window and it decreases the service benefit.

Marginal cost calculation in system optimal dynamic traffic assignment (SODTA)

Ghali, M.O. and Smith, M.J., 1995. A model for the dynamic system optimum traffic assignment problem. Transportation Research Part B: Methodological, 29(3), pp.155-170.

- **Step 1**: Build virtual pickup and drop-off links in physical traffic networks, and its service pricing is converted to generalized link travel cost
- **Step 2**: find one initial solution as the input
- **Step 3**: Perform network loading within a space-time-state network
  - 3.1 use cumulative arrival and departure counts to derive the link marginal travel cost.
  - 3.2 update the marginal service link benefit of passengers (not served or served by multiple vehicles)

**Step 4**: find the new least-marginal-cost route for each vehicles, and go to step 3; otherwise, stop.

Path marginal cost is probably related to the Lagrangian multipliers in ADMM and the dual prices in Dantzig-Wolfe decomposition.

#### Capture queue spillback:

Inflow arc capacity constraint:

$$\sum_{w} x_{i,j',t-FFTT_{i,j}+1,t,w,w'} \le Cap_{i,j',t-FFTT_{i,j}+1,t}, \forall (i,j') \in L_{inflow}, \forall t$$

$$\tag{11}$$

Outflow arc capacity constraint:

$$\sum_{w} x_{j',j,t,t+1,w,w'} \le y_{j',j,t,t+1}, \forall (j',j) \in L_{outflow}, \forall t$$

$$(12)$$

Outflow arc capacity balance constraint at points without merger and diverge:

$$y_{j',j,t,t+1} \le Cap_{j,i,t+1,s} \tag{13}$$

Outflow arc capacity balance constraint at merger points:

$$\sum_{(j',t)} y_{j',j,t,t+1} \le Cap_{j,i,t+1,s}, \forall (j,t+1) \in A_m$$
 (14)

Outflow arc capacity balance constraint at diverge points:

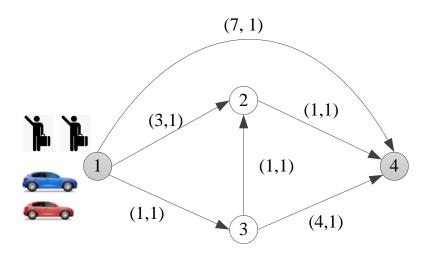

$$y_{j',j,t,t+1} \le \sum_{(i,s)} Cap_{j,i,t+1,s} \,\forall (j,t+1) \in A_d \tag{15}$$

Link storage capacity constraint:

$$\sum_{w} x_{j',j',t-1,t,w,w'} + \sum_{w} \sum_{s=t-FFTT_{i,j'}}^{t-1} x_{i,j',s,t,w,w'} \le Len_{i,j'} \times n_{i,j'} \times Jam_{i,j'}, \forall (i,j') \in L_{inflow}, \forall t$$
 (16)

- There are 2 vehicles, and each vehicle picks up one passenger from origin node 1 to destination node 4.
- Our goal is to minimize the total vehicle travel cost by using Dantzig-Wolfe decomposition approach.

Path ID	Node Sequence	Path Cost	Path Trajectory
Path 1	1→2→4	4	
Path 2	1-3-4	5	•
Path 3	1→4	7	
Path 4	1-3-2-4	3	

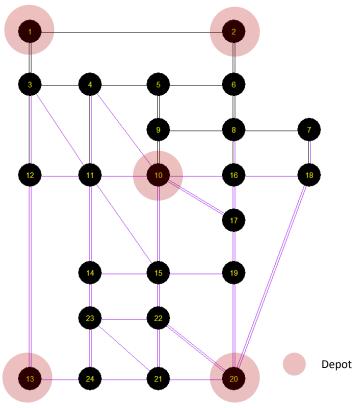

(link cost, link capacity)

Variable  $\lambda_i$  is the weight of path i of total demand;  $\mu_{i,j}$  is the dual price of capacity constraint of link (i,j);  $\pi$  is the dual price of path flow weight constraint.

	Sub problem	New column: path 4
Iteration 1	Master	$\lambda_4 = 1$ , $\mu_{1,3} = -1$ , $\mu_{1,2} = 0$ , $\mu_{3,2} = 0$ , $\mu_{2,4} = 0$ , $\mu_{3,4} = 0$ ,
	problem	$\mu_{1,4} = 0, \pi = 2$
	Sub problem	New column: path 1
Iteration 2	Master	$\lambda_1 = 1$ , $\mu_{2,4} = -1$ , $\mu_{1,2} = 0$ , $\mu_{3,2} = 0$ , $\mu_{1,3} = 0$ , $\mu_{3,4} = 0$ ,
	problem	$\mu_{1,4} = 0, \pi = 2$
Iteration 3	Sub problem	New column: path 3
	Master	$\lambda_4 = 0.5$ , $\lambda_3 = 0.5$ , $\mu_{1,3} = -1$ , $\mu_{2,4} = -3$ , $\mu_{1,2} = 0$ , $\mu_{3,2} = 0$
	problem	$0, \mu_{3,4} = 0, \mu_{1,4} = 0, \pi = 14$
Iteration 4	Sub problem	New column: path 2
	Master	$\lambda_1 = 0.5, \lambda_2 = 0.5, \mu_{1,3} = -2, \mu_{2,4} = -2, \mu_{1,2} = -1, \mu_{3,2} =$
	problem	$0, \mu_{3,4} = 0, \mu_{1,4} = 0, \pi = 14$

The reduced cost is 4 + 5 - (-2) - (-2) - (-1) - 14 = 0 and reach the optimal solution.

Requests with pickup and drop-off and time windows under capacitated networks

### **Dantzig-Wolfe decomposition algorithm solution:**

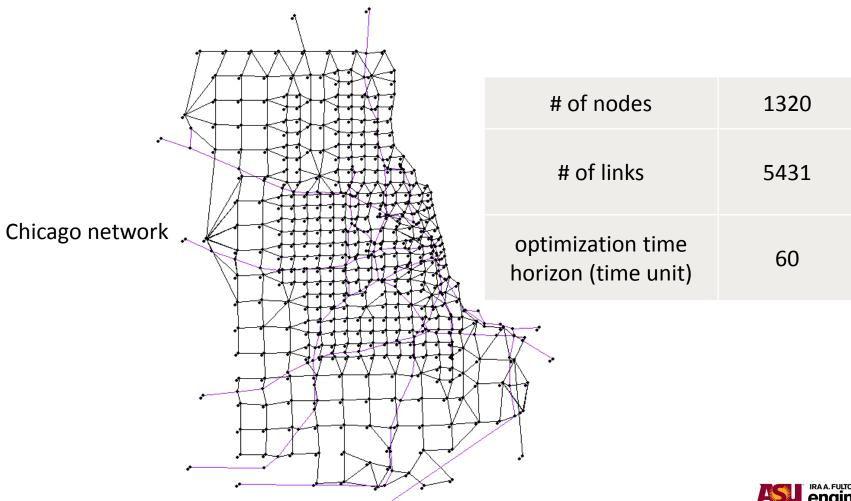

- ☐ Each passenger has specific pickup and drop-off location and time windows
- ☐ The vehicle benefit of serving one passenger is 20
- ☐ The vehicle waiting cost is the half of the waiting time

	Number of required vehicles	Total travel cost
Initial solution	30	1096
vehicle carrying capacity is 1	27	967.5
vehicle carrying capacity is 2	25	869.5

#### Take vehicle 9 as an example:

- ☐ In initial solution: picks up passenger 17 -> drops off passenger 17;
- □ Vehicle carrying capacity is 1: picks up passenger 17 -> drops off passenger 17-> picks up passenger 29 -> drops off passenger 29
- □ Vehicle carrying capacity is 2: picks up passenger 17 -> drops off passenger 17-> picks up passenger 30-> picks up passenger 29-> drops off passenger 29-> drops off passenger 30-> drops off pas

Requests with pickup only and time windows under capacitated networks

#### **Step A: Prior generation of column pool**

#### **Scenario 1:** Sample data set

- 10 pairs of vehicle groups and passenger groups.
- Each pair has 243 vehicles and 387 passengers trip requests
- The space-time arc capacity in each minute is 5.
- Vehicle carrying capacity is 1
- 2430 binary variables and 332,160 constraints

### **Scenario 2:** Sample data set

- o 20 pair of vehicle groups and passengers groups.
- o Each pair has 243 vehicles and 387 passengers trip requests
- The space-time arc capacity in each minute is 5.
- Vehicle carrying capacity is 1
- 4860 binary variables and 338,460 constraints

### **Solution from Agent-based ADMM**

#### Scenario 1:

- o 1789 vehicles find their paths/columns to serve 1084 passengers
- o 23,357 space-time arcs are generated based on vehicles' space-time paths
- o Computation time: about 70 seconds each iteration

#### Scenario 2:

- 3686 vehicles find their paths/columns to serve 2226 passengers
- o 36,454 space-time arcs are generated based on vehicles' space-time paths
- Computation time: about 140 seconds each iteration

Remark: each passenger has a specific pickup location, time window and destination, and vehicle can only pick up passengers within a same pair of groups read Full Tonschool engineeri

#### **Step B: Flow-based ADMM implemented by C++**

### **Experiment 1:**

- 1084 passenger groups and each passenger group has 4 passenger trip requests
- The space-time arc capacity in each minute is 35
- o 1789 positive continuous variables and 24,441 constraints
- o Computation time: 700 CPU seconds for running 250 iterations

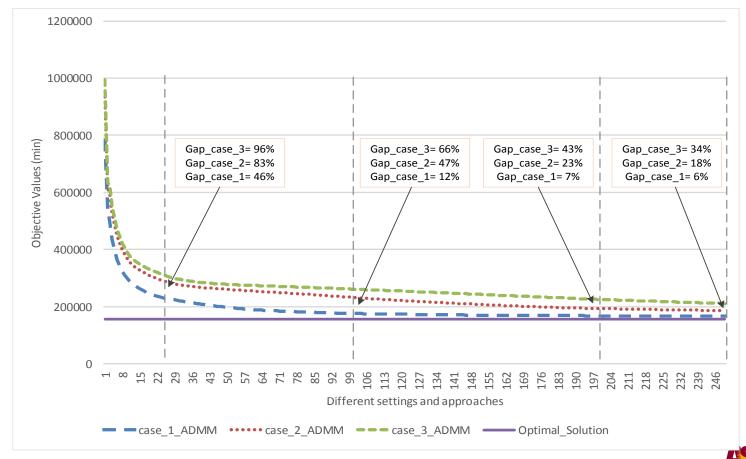

### **Experiment 2:**

- o 2226 passenger groups and each passenger group has 2 passenger trip requests
- The space-time arc capacity in each minute is 35
- o 3686 positive continuous variables and 38,680 constraints
- Computation time: 2735 CPU seconds to finish 250 iterations

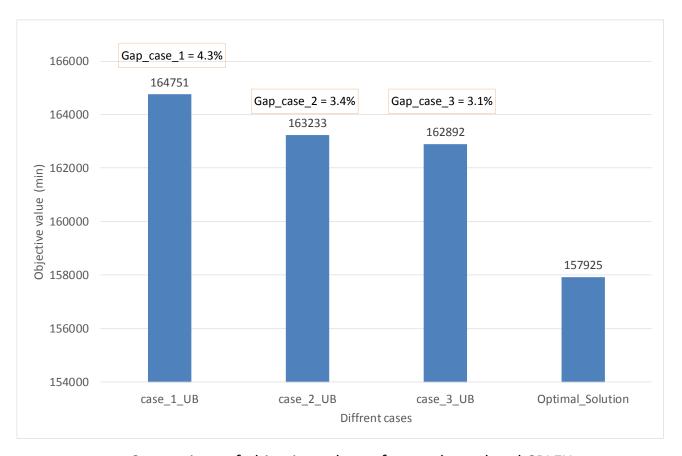

#### **Experiment 1**

Case 1:  $\rho_1 = 3$  and  $\rho_2 = 1$ ; Case 2:  $\rho_1 = 3$  and  $\rho_2 = 3$ ; Case 3:  $\rho_1 = 3$  and  $\rho_2 = 5$ .
